## 1 Compressed Sensing

Assume **A** is an  $m \times n$  matrix, n > m. Consider the problem

$$\begin{aligned}
\min & \|\mathbf{x}\|_0 \\
\text{s.t.} & \mathbf{A}\mathbf{x} = \mathbf{b}.
\end{aligned} \tag{1}$$

Using MIO, we reformulate this problem as

min 
$$\sum_{i=1}^{n} z_{i}$$
s.t.  $\mathbf{A}\mathbf{x} = \mathbf{b}$ , (2)
$$-Mz_{i} \leq x_{i} \leq Mz_{i} \qquad i = 1, \dots, n,$$

$$z_{i} \in \{0, 1\} \qquad i = 1, \dots, n.$$

Next, consider the problem

$$\min \|\mathbf{x}\|_1 
\text{s.t. } \mathbf{A}\mathbf{x} = \mathbf{b}.$$
(3)

Using linear optimization, we can reformulate this problem as

min 
$$\sum_{i=1}^{n} y_{i}$$
s.t.  $\mathbf{A}\mathbf{x} = \mathbf{b}$ , 
$$-y_{i} \le x_{i} \le y_{i} \qquad i = 1, \dots, n.$$
 (4)

## 2 Algorithmic Framework for Regression using MIO

### 3 First Order Method

Here, we derive a first order method following the notes from Lecture 2 - Best Subset Selection. Consider the problem

$$\min_{\boldsymbol{\beta}} \quad g(\boldsymbol{\beta}) := \|\mathbf{y} - \mathbf{X}\boldsymbol{\beta}\|_{2}^{2} + \Gamma \|\boldsymbol{\beta}\|_{1}$$
s.t.  $\|\boldsymbol{\beta}\|_{0} < k$ . (5)

Since  $g(\boldsymbol{\beta})$  is convex and  $\|\nabla g(\boldsymbol{\beta}) - \nabla g(\boldsymbol{\beta}_0)\| \le \ell \|\boldsymbol{\beta} - \boldsymbol{\beta}_0\|$ , it follows that for all  $L > \ell$ 

$$g(\boldsymbol{\beta}) \leq Q(\boldsymbol{\beta}) := g(\boldsymbol{\beta}_0) + \nabla g(\boldsymbol{\beta}_0)^T (\boldsymbol{\beta} - \boldsymbol{\beta}_0) + \frac{L}{2} \|\boldsymbol{\beta} - \boldsymbol{\beta}_0\|_2^2 + \Gamma \|\boldsymbol{\beta}\|_1.$$
 (6)

To find feasible solutions, we solve the following problem

$$\min_{\boldsymbol{\beta}} \quad Q(\boldsymbol{\beta}) \\
\text{s.t.} \quad \|\boldsymbol{\beta}\|_{0} < k. \tag{7}$$

This is equivalent to

$$\min_{\boldsymbol{\beta}} \quad \frac{L}{2} \left\| \boldsymbol{\beta} - \left( \boldsymbol{\beta}_0 - \frac{1}{L} \nabla g(\boldsymbol{\beta}_0) \right) \right\|_2^2 - \frac{1}{2L} \| \nabla g(\boldsymbol{\beta}_0) \|_2^2 + \Gamma \| \boldsymbol{\beta} \|_1$$
s.t.  $\| \boldsymbol{\beta} \|_0 \le k$ , (8)

which reduces to the following plus a constant term:

$$\min_{\boldsymbol{\beta}} \quad \frac{L}{2} \|\boldsymbol{\beta} - \mathbf{u}\|_{2}^{2} + \Gamma \|\boldsymbol{\beta}\|_{1}$$
s.t. 
$$\|\boldsymbol{\beta}\|_{0} \leq k.$$
(9)

For the vector  $\mathbf{u} \in \mathbb{R}^p$ , let  $(1), (2), \ldots (p)$  be the indices of the order statistics  $|u_{(1)}| \geq |u_{(2)}| \geq \ldots \geq |u_{(p)}|$ . At the optimal solution  $\boldsymbol{\beta}^*$  to problem 9, we have  $|\beta_{(1)}^*| \geq |\beta_{(2)}^*| \geq \ldots \geq |\beta_{(p)}^*|$ , which implies that  $|\beta_{(k+1)}^*| = |\beta_{(k+2)}^*| = \ldots = |\beta_{(p)}^*| = 0$ . For  $i \leq k, \beta_{(i)}^*$  is the optimal solution to the following unconstrained single variable problem:

$$\min_{\beta_{(i)}} \frac{L}{2} (\beta_{(i)} - u_{(i)})^2 + \Gamma |\beta_{(i)}|. \tag{10}$$

Problem 10 has closed form solution

$$\beta_{(i)}^* = \begin{cases} u_{(i)} - \frac{\Gamma}{L} \operatorname{sign}(u_{(i)}), & \text{if } |u_{(i)}| \ge \frac{\Gamma}{L}, \\ 0, & \text{otherwise.} \end{cases}$$
 (11)

Thus, the optimal solution to problem 9 is  $\beta^* = \mathbf{H}_k(\mathbf{u})$ , where

$$(\mathbf{H}_k(\mathbf{u}))_i = \begin{cases} u_{(i)} - \frac{\Gamma}{L} \operatorname{sign}(u_{(i)}), & \text{if } |u_{(i)}| \ge \frac{\Gamma}{L} \text{ and } i \le k, \\ 0, & \text{otherwise.} \end{cases}$$
(12)

Using this update iteratively to determine the  $\beta_i$ 's, we obtain the following first order method:

#### Algorithm 1

Input:  $g(\boldsymbol{\beta}), L, \epsilon$ .

Output: A first order stationary solution  $\beta^*$ .

- 1. Initialize with  $\boldsymbol{\beta}_1 \in \mathbb{R}^p$  such that  $\|\boldsymbol{\beta}_1\|_0 \leq k$ .
- 2. For  $m \geq 1$

$$\boldsymbol{\beta}_{m+1} \leftarrow \mathbf{H}_k(\boldsymbol{\beta}_0 - \frac{1}{L} \nabla g(\boldsymbol{\beta}_0))$$

3. Repeat Step 2, until  $g(\boldsymbol{\beta}_m) - g(\boldsymbol{\beta}_{m+1}) \le \epsilon$ .
